You think the way Internet is changing on our minds and future. Edited by John Brockman.
This is Your Brain on Internet

The representation of the saliency structure of the world: the pre-frontal cortex is the location where it allows the brain to build up an image of the world. However, we are so good at unconscious learning, one advantage of unconscious learning is that it allows us to build up an image of the world without our conscious involvement.

In the case of social interaction, it is less clear whether the pre-frontal cortex is involved. Social interaction, especially in the context of face-to-face communication, requires more effort than simple visual processing. However, when we think about social interaction, the pre-frontal cortex is involved. This is because social interaction requires that we understand the intentions and emotions of others. The pre-frontal cortex is involved in this process as it allows us to interpret the intentions and emotions of others.

In conclusion, the pre-frontal cortex plays a crucial role in the representation of the world. It allows us to build up an image of the world, and this image is used to interpret the intentions and emotions of others. This process is essential for social interaction, and it is mediated by the pre-frontal cortex.
